

MARKOVSKIY, N.I.

✓ 178. NEW COAL-BEARING REGIONS IN THE EASTERN PART OF THE RUSSIAN PLATFORM. Markovskiy, N.I. (Dokl. Akad. Nauk SSSR (Rep. Acad. Sci. U.S.S.R.), 21 June 1956, vol. 108, (6), 1148-1151). The geology and supposed mode of formation of the coal are described. Seams of young coal up to 17 m thick have been found, the thickest at Sul'jevo in south-eastern Tatariya. The coal contains 14.6% ash, 3.6% inherent moisture, 4.3% total sulphur, 77.4% carbon and 4.1% hydrogen (the latter two on a dry ash-free basis). (L).

TITLE:

Coal-Bearing Capacity and Forecasts of Oil and Gas Incidence (Uglenosnost' i prognoz neftegazonosnosti)

PERIODICAL:

Priroda, 1959, Nr 4, pp 89-93 (USSR)

ABSTRACT:

The author indicates that as a result of detailed research into the terrigenous layers of the Lower Carbonic period in the south Russian platform, a specific correlation between its coal and oil deposits has been established, which again leads to determining certain regions and regularities in their spatial distribution. This correlation conditioned by the joint development process of organic life on the continent and the sea has been determined by the concrete paleogeographic situation in general (see figure 1). It has been established by prospecting methods that the West Siberian depression is covered with Mesokainozoic sediments reaching a thickness of

Card 1/2

SOV/26-59-4-21/43

## Coal-Bearing Capacity and Forecast of Oil and Gas Incidence

3,500 m and including almost all stratigraphical horizons of the Jurassic, Chalk, Paleogene and sometimes Neogen periods. For instance, it is known that there are oil and gas deposits connected with the terrigene layers of the Jurassic period in the Ural-Emba oil and gas province; the Tertian period provided even more favorable conditions for coal and oil formations (54% of the world's coal and 53% of the world's oil deposits falls into this period). Moreover, the Mesocenozoic deposits of the West Siberian depression in general hold good prospects for oil and gas occurrences. Therefore, to achieve successful prospecting it is necessary to study and determine the distribution of ancient seas and continents, their borders and time limits. There are 3 maps and 1 diagram.

TITLE: Field-Type Universal Saltmeter SM-6  
(Polevoy universal'nyy solemer SM-6)

PERIODICAL: Les. kh-vo, 1956, Nr 10, pp 92-93

ABSTRACT: Alternating current is used in SM-6 saltmeter for measuring salinity of ground or surface waters, of soils, etc., under field conditions, thus eliminating polarization of the electrodes. The salinity measurement range for water is 10 g/l; for soils, up to 5% of their weight. The instrument can be supplied from an AC line or from internal dry batteries. Measurement of overall salinity is based on electric conductivity of water or aqueous extraction of soil. The measuring unit is, in fact, an AC ohmmeter with a detector-type milliammeter. A vibrapack is used in case of dry-battery supply. A thermistor is used for temperature compensation. A plexiglas 15-ml cup with graphite electrodes in its walls serves as a pickup; converting the instrument reading

Card 1/2

SOV/ 112-58-1-755

Field-Type Universal Saltmeter SM-6

into salt-content units is accomplished by calibration curves. Instrument error ranges from 1% to 5%, depending on the concentration of the solution in question.

TITLE: Determination of the photoelasticity of a fine-grained annealed silver chloride constant subjected to elastic and plastic deformation

SOURCE: IVUZ. Chernaya metallurgiya, no. 3, 1964, 81-86

TOPIC TAGS: Photoelasticity, AgCl, Mo, bending test, tensile test, residual stress, elastic deformation, plastic deformation, AgCl deformation

ABSTRACT: The authors investigated the photoelastic properties of fine-grained polycrystalline AgCl subjected to plastic and elastic deformation after annealing. Single crystals with a diameter of 31 mm and a height of 120 mm were grown in Mo glass crucibles in a vertical tubular electric furnace with a rated temperature gradient. The grown crystal was cut into 40-45 mm cylinders and reduced to 2 to 3 mm-thick plates that were annealed for recrystallization. With a 95% deformation rate 10-hour holding was found to be optimal. Maximum grain size was 0.05 mm and no residual stresses were detected in the specimens. Bending - tensile tests yielded the relationship between the values of the optical difference in

Card 1/2

ACCESSION NR: AP4022896

the occurrence of  $\delta$  and the actual stress  $\sigma$ , making it possible to express the law of photoelasticity as follows:

$$\delta = Cd\sigma$$

where C is the optical constant, d - the thickness of the specimen and  $\sigma$  - the actual tensile stress. The value of the optical constant was equal to (60 to 70)  $\times 10^{-7} \text{ cm}^2/\text{kg}$  after tensile tests and (50 to 56)  $\times 10^{-7} \text{ cm}^2/\text{kg}$  after pure bending tests. A fibrous structure appeared after the application of loads in excess of  $\sigma = 1.5 \text{ to } 1.8 \text{ kg/mm}^2$ . The determination of the optical constant for fine-grained pseudoisotropic silver chloride provides the possibility of a qualitative and quantitative analysis of the stressed state of pseudoisotropic crystalline materials under the effect of plastic and elastic deformation.

AUTHOR: Markovskiy, V. Yu.; Polukhin, P.I.; Shaskol'skaya, M.P. B

TITLE: A method for the simultaneous observation of stresses and strains in crystalline substances in the elastic and plastic regions 10 18

SOURCE: IVUZ. Tsvetnaya metallurgiya, no. 6, 1964, 109-115

TOPIC TAGS: crystal stress, crystal strain, elastic deformation, plastic deformation, silver chloride, stress strain diagram, polarization optics, photoelastic coating 24

ABSTRACT: A new technique is described for the simultaneous and direct study of the actual and residual stresses and strains by a polarization-optical method. The essential feature of the technique consists in observing the stresses in a polycrystalline material (AgCl) and at the same time studying the strains by the method of photoelastic coatings. In the latter method, a reflecting layer of metallic silver is deposited on the polycrystalline AgCl, and an optically sensitive coating is placed on top of that layer. Two patterns of isochromes (one in AgCl and one in the coating) are then observed on two separate screens, the specimens being subjected to loads. The apparatus and method of operation are described in detail. The technique can be successfully applied to the study of single crystals and coarse-grained polycrystalline samples of any crystalline substance

Card 1/2

(or amorphous material) producing an optical effect when subjected to stresses.  
Quantitative data were obtained on the distribution of residual stresses and strains  
in a sample of fine-grained polycrystalline AgCl subjected to pure plastic bending. The  
data obtained for silver chloride by the method of photoplasticity can be extended to metals  
when the simulation laws are observed. Orig. art. has: 5 figures and 1 formula.

TITLE: Wear-resistance of High-strength Cast Iron Employed in the Manufacture of Tractors (Iznosostoykost' vysokoprochnogo chuguna, primenayemogo v traktorostroyenii)

PERIODICAL: Nauchn. tr. In-ta mashinoved. i s.-kh. mekhan. AN UkrSSR, 1958, Vol 6, pp 33-52

ABSTRACT: Weighing methods and radioactive isotopes were employed in wear-resistance tests performed on cast iron with spheroidal graphite (CISG) paired with various other types of cast iron and steel. The tests were carried out with and without lubrication under varying specific pressures. A horizontal plateau observed on curves representing the wear of pearlitic cast iron as a function of the specific pressure indicates that within a certain interval the wear is independent of the specific pressure. The fact that wear is not affected by an increase in pressure is attributable to an optimal saturation of friction surfaces with austenite that is formed during friction. For each pair (at a given velocity of friction) there exists a critical loading under

Card 1/2

SOV/137-58-10-21553

Wear-resistance of High-strength Cast Iron (cont.)

which both the nature and the magnitude of wear are altered (the beginning of seizing). Under dry friction, pressures up to 40 kg/mm<sup>2</sup> (at velocities up to 1 m/sec) and 25 kg/mm<sup>2</sup> (at a velocity of 3 m/sec) are permissible for components made of CISG with a pearlite or pearlite-ferrite structure. With full lubrication the specific pressures may be increased to 80 kg/mm<sup>2</sup> (at a velocity of 1 m/sec). Operational tests performed on D-54 Diesel units with crankshafts made of CISG and of steel demonstrated that crank-pin wear is smaller in the case of the CISG crankshafts. The CISG crankshafts contained 15-25 and 40-60% of structural ferrite; the wear of the first group (containing 15-25% ferrite) was found to be somewhat greater than the wear of the second group.

TITLE: Some features of the state of metal surfaces deformed  
by frictionSOURCE: Soveshchaniye po voprosam teorii sukhogo treniya i izla-  
zovaniya chastits iznosa pri sukhom trenii. Riga 1981.  
129-137

TEXT: The authors subjected high-strength cast iron, containing globular graphite, to dry sliding friction and to axial compression and studied the formation of wear-resisting surface layers. X-ray diffractograms, obtained by L. I. Rybak with a  $\gamma$ PC-50M (URS-50I) instrument, showed that coherent scattering regions in the surface of cast iron were smaller  $(1.8 - 3.5) \times 10^{-7}$  cm. after dry friction than after axial compression,  $(2.0 - 4.6) \times 10^{-7}$  cm. Block fragmentation increased on increase of pressure during dry friction, irrespective of the actual structure of cast iron. In the

Some features of ...

case of axial compression an increase of pressure beyond a certain deformation (30%) did not alter block dimensions. At constant pressure dry friction produced stronger block fragmentation in ferrite than in pearlite; the converse occurred in axial compression. Distortions of the second kind,  $\Delta a/a$ , depended on the mode of deformation and on crystal structure. Under dry friction the distortions in ferrite always increased in extent with increase of applied pressure, but in pearlite a pressure beyond a certain value left these distortions unaffected. In axial compression which produced deformation greater than 20 - 30% an increase of applied pressure did not affect distortions in pearlite and ferrite. Dry friction produced very rapid local changes of temperature ( $\geq 10^4$  deg/sec), as found with a microthermal couple and a string gallograph MPO-2 (MPO-2). Such temperature changes favored formation of austenite in surface layers which hardened these layers. This did not happen under axial compression. Under sole condition of dry friction an increase of applied pressure or of sliding velocity decomposed the freshly formed  $\gamma$ -phase and caused precipitation.

tion of carbide; this raised the surface hardness and wear resistance. It was also found that dry friction intensified diffusion in surface layers of one metal and between surfaces of two metals in friction. The surface layers produced by dry friction had a fine-grain structure with occlusions at least 100 times smaller than those present initially in cast iron. Vsesoznayaya konferentsiya po treniyu i iznosu v mashinakh. 3d.  
1958.

Izdat. 1 iznosostoykost'. Antifrictionnye materialy (Wear and  
Wear Resistance. Antifricion Materials) Moscow Izdvo AM  
SSSR, 1960. 273 p. Errata slip inserted. 3,500 copies printed.  
(Series: Its: Treniy, v. 1)

Sponsoring Agency: Akademiya nauk SSSR. Institut mashinovedeniya.

Resp. Ed.: N. M. Kharushchov, Professor; Eds. of Publishing  
House: N. Ya. Klebanov, and S. L. Orpik; Tech. Ed.:  
F. V. Polyakova.

PURPOSE: This collection of articles is intended for practicing  
engineers and research scientists.

CONTENTS: The collection published by the Institut mashinovedeniya,  
AM SSSR (Institute of Machine Sciences) contains papers presented at the III Vsesoznaya Kon-  
ferentsiya po treniyu i iznosu v mashinakh (Third All-Union  
Conference on Friction and Wear in Machines) which was held  
April 9-15, 1958. Problems discussed were:  
1) Hydrodynamic Theory of Lubrication and Friction Bearings  
(Chairman: Ye. M. Gut'yar, Doctor of Technical Sciences, and  
A. E. D'yachkov, Doctor of Technical Sciences); 2) Lubrication  
and Lubricant Materials (Chairman: G. V. Vinogradov, Doctor of  
Chemical Sciences); 3) Dry and Boundary Friction (Chairmen:  
B. V. Derzhin, Corresponding Member of the Academy of Sciences  
USA, and I. V. Krugel'skiy, Doctor of Technical Sciences);  
4) Wear and Wear Resistance (Chairman: N. M. Krushchov,  
Doctor of Technical Sciences); and 5) Friction and Antifriction  
Materials (Chairmen: I. V. Krugel'skiy, Doctor of Technical  
Sciences, and N. M. Krushchov, Doctor of Technical  
Sciences). Chairman of the General Assembly (on the first and  
last day of the conference) was Academician A. A. Blagonravov.  
L. Yu. Frushanskiy, Candidate of Technical Sciences, was sci-  
entific secretary. The transactions of the conference were  
published in 3 volumes, of which the present volume is the  
first. This volume contains articles concerning the wear and  
wear resistance of antifriction materials. Among the topics  
covered are: modern developments in the theory and experi-  
mental science of wear resistance of materials, specific data  
on the wear resistance of various combinations of materials,  
methods for increasing the wear resistance of certain materials,  
the effects of friction and wear on the structure of materials,  
the mechanism of the seizing of metals, the effect of various  
types of lubricating materials on metal fatigue, abrasive wear or a  
wide variety of materials and components under many different  
conditions, modern developments in antifriction materials, and  
the effects of finish machining on wear resistance. Many per-  
sonalities are mentioned in the text. References accompany most  
of the articles.

TITLE: The Effect of Friction and Plastic Deformation on the  
Fine Structure of High-Strength Cast Iron

PERIODICAL: Fizika metallov i metallovedeniye. 1961, Vol.11, No.2,  
pp.296-301

TEXT: Pearlitic and ferritic cast irons containing (wt.%)  
3.64 C, 2.42 Si, 0.60 Mn, 0.045 P, 0.0322 S, 0.19 Cr and  
0.96 Mg, were used in the present investigation. Cylindrical  
specimens were subjected to uniaxial compression to attain  
deformation ranging from 7 to 75% the effect of deformation on  
the distortions of the second type ( $\Delta a/a$ ) and on the size D of  
the regions of coherent scattering of X-rays was studied. In  
addition, the effect of sliding friction (at a constant speed of  
3.25 m/sec) on these characteristics was studied. The results  
are reproduced graphically in Fig.1 and 2. In Fig.1, the degree  
of lattice distortion of the second type ( $\Delta a/a \cdot 10^{-3}$ , right-hand  
scale) and the dimension of the mosaic blocks ( $D \cdot 10^{-6}$  cm, left-  
hand scale) are plotted against the degree (%) of deformation,

## The Effect of Friction ...

curves 1 and 2 relating to pearlitic and ferritic cast irons, respectively. In Fig. 2,  $\Delta a/a$  and D are plotted against the specific pressure ( $\text{kg}/\text{cm}^2$ ) applied during the friction tests on pearlitic (curve 1) and ferritic (curve 2) cast irons. It has been established that both uniaxial compression and friction loads cause considerable distortion of the crystal lattice and bring about a decrease in the size of the mosaic blocks in the matrix, each effect being more pronounced in the pearlitic cast iron. Similarly, microhardness of pearlitic cast iron, subjected to either type of deformation, is higher than that of the ferritic alloy. In the surface layers of specimens of both types of cast iron, subjected to friction loading, a transformation takes place, as a result of which austenite is formed and the quantity of cementite in the alloy increases, the content of both these phases increasing with increasing magnitude of the applied pressure. It was concluded that the results of the present investigation can be used to evaluate the resistance to deformation of materials operating under friction loads. There are 4 figures, 2 tables and 2 Soviet references.

TITLE: On the effect of nuclear radiations on the properties of metallic alloys.

SOURCE: Struktura i svoystva litykh splavov. no.1. Inst. lit. proizv. AN USSR.  
Kiev, Izd-vo AN UkrSSR, 1962. 67-75.

TEXT: The paper provides a discussion based on a literature survey, primarily of English-language Western publications. It discusses the effects of nuclear neutron radiation on metallic alloys in the sense of the Seitz and Brinkmann theories. The effects of neutron radiation on the hardness, tensile strength, and yield point of various steels, including SAE 1018 and 1095, stainless steel 304 and 316, and ASTM A212B and -A242 with various grain sizes, are summarized in several extensive tables. Radiation impingement on cast structural steels, especially when in the normalized or annealed state, can substantially increase the strength of such materials, affording them a strength that approaches that of work-hardened steel. It is suggested that investigations be performed to establish the changes in the properties of irradiated cast materials versus the radiation dose and to ascertain the minimal radiation dose that affords the desired effect. It appears advisable also to undertake an investigation of the effect of neutron radiation on the heat

TITLE: Changes in the antifriction and strength characteristics of structural materials subjected to neutron irradiation

SOURCE: Fiziko-khimicheskaya mehanika materialov, v. 1, no. 5, 1965, 552-556

TOPIC TAGS: steel, copper, antifriction material, antifriction metal, neutron irradiation, nuclear reactor material, cast iron, irradiation effect, fabricated structural metal, metal physical property, stress relaxation

ABSTRACT: This work studies the changes in the antifriction parameters of some structural metals and alloys subjected to various degrees of neutron irradiation in an operational neutron reactor. Simultaneously, the changes in some of the strength characteristics of the materials are also determined. The materials studied were steel No. 45, various types of cast iron, copper, and SB-30 lead bronze. The results obtained give grounds to conclude that the accelerated process of stress relaxation under the effect of irradiation may take place not only for stressed materials but also for metastable hardened structures. An attempt

Card 1/2

L 12165-66

is made to explain the time-dependent decrease in the strength of steel subjected to irradiation, but it is not sufficiently grounded. Further experimental work is required. The work performed showed, however, that the materials tested, after undergoing a stage of relative decrease in strength, obtain under prolonged neutron irradiation satisfactory antifriction and strength characteristics and may be successfully used in friction joints. Work in this field, according to the present authors, should be directed toward the study of the wear resistance and setting of materials under neutron irradiation, in vacuum, at high temperatures, and in special media. TITLE: Antifriction characteristics of neutron-irradiated steel /s

SOURCE: Atomnaya energiya, v. 18, no. 1, 1965, 72-73

TOPIC TAGS: neutron irradiation, radiation damage, steel, wear resistance, hardness

ABSTRACT: The purpose of the investigation was to determine the changes in the antifriction properties of medium-carbon steel under the influence of neutron irradiation under real conditions prevailing in a nuclear reactor, and to determine the minimum integral neutron flux causing a change in these properties. The samples tested were pins of St.45 steel (0.49% C, 0.56% Mn, 0.27% Si) 3 mm in diameter and 10 mm long. The samples were irradiated with different integral neutron fluxes and tested for hardness and for wear together with

Card 1/3

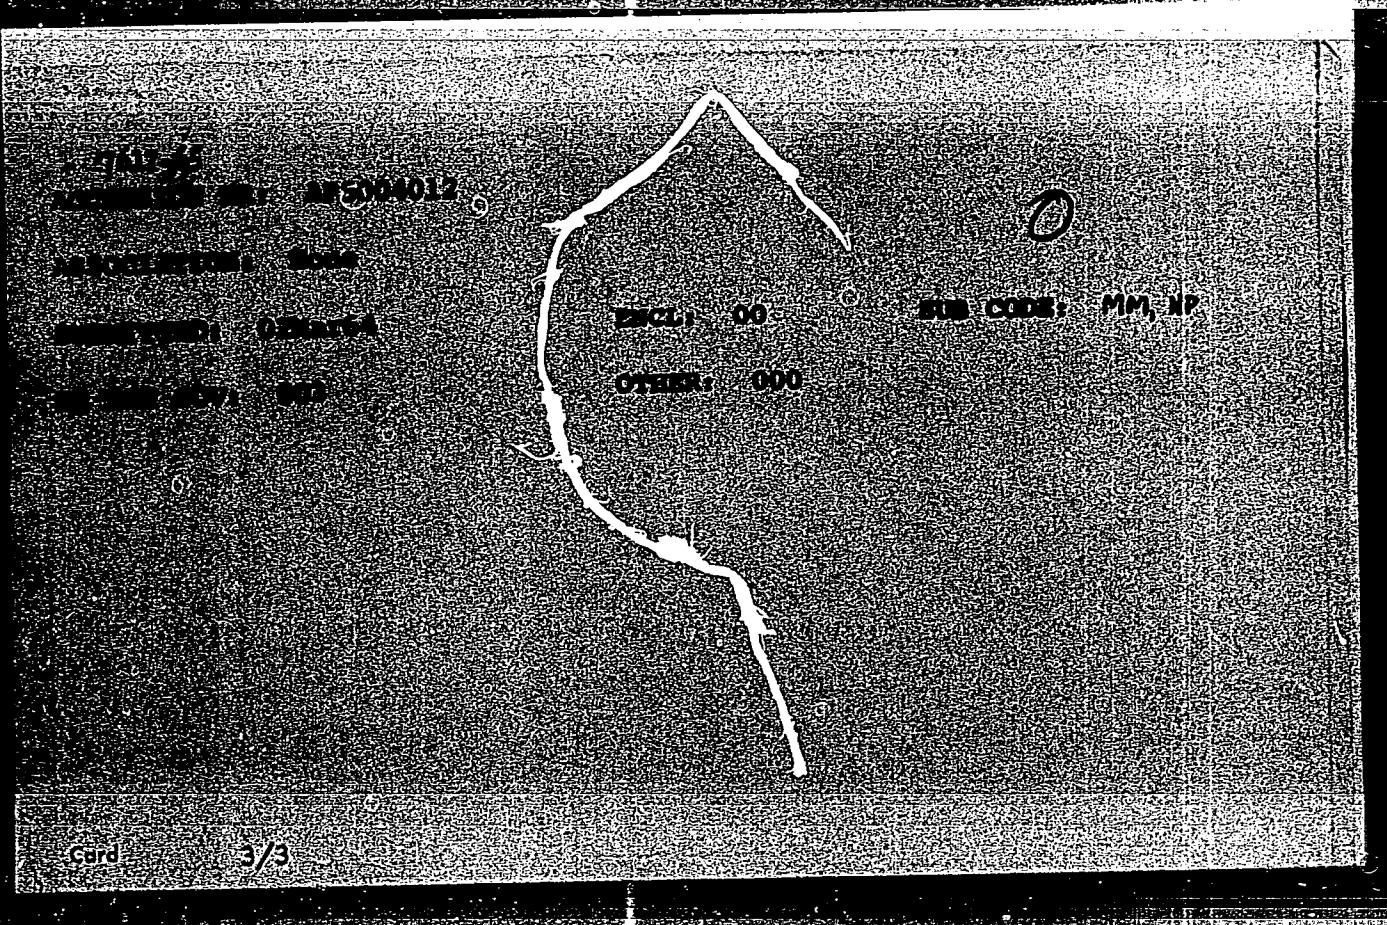

617-65  
ACCESSION NR. AP5004012

non-irradiated samples. The tests for wear were made with a laboratory setup described elsewhere (Ye. A. Markovskiy and V. I. Stetsenko, Zavodsk. laboratoriya No. 4, 503, 1958). The friction coefficient was measured with inductive pickups connected to an automatic recording galvanometer. The tests were made in fluxes of  $10^{16}$ ,  $10^{17}$ ,  $10^{18}$ ,  $10^{19}$ , and  $10^{20}$  neut/cm<sup>2</sup> in vertical channels of the nuclear reactor of Institut fiziki (Physics Institute) AN UkrSSR. The results have shown that the hardness has a minimum near  $10^{17}$  neut/cm<sup>2</sup> for steel heat treated in different manners, and that at small radiation doses the wear resistance of annealed steel decreases, with the maximum wear occurring at  $10^{18}$  neut/cm<sup>2</sup>. Further increase in the dose reduces the wear, and when the flux is  $10^{20}$  neut/cm<sup>2</sup> the wear is actually 30% lower than for non-irradiated samples. The reduction in hardness ranges from 2% for normalized steel to 8% for annealed steel. The effect of temperature is also briefly discussed.

TITLE: Effect of irradiation with neutrons on the ferritic-pearlitic structure of iron-carbon alloys

SOURCE: Fizika metallov i metallovedeniye, v. 19, no. 2, 1965, 306-308

TOPIC TAGS: carbon steel, malleable iron, steel irradiation, malleable iron irradiation, pearlite, ferrite, neutron irradiation, irradiated steel property, irradiated malleable iron property, irradiated pearlite property, irradiated ferrite property

ABSTRACT: Specimens of carbon steel (0.49% C, 0.56% Mn, 0.27% Si) and malleable iron (3.13% C, 0.65% Mn, 3.33% Si) annealed to a ferrite-pearlite structure with respective ferrite contents of 50 and 10% were irradiated with neutron doses of  $10^{16}$  to  $10^{20}$  neutron/cm<sup>2</sup>. The hardness, tensile strength, yield strength, and wear resistance of both metals first dropped, but then increased with increasing dosage. The effect of irradiation on the microhardness of pearlite in both materials was almost identical. The microhardness dropped at first and then increased. The microhardness of ferrite in steel rose continuously and that in iron dropped slightly.

Card 1/2

L 32036-65

ACCESSION NR: AP5006340

18  
2  
with prolonged irradiation. Thus, the decrease in hardness is associated primarily with softening of pearlite and may be attributed to radiation-induced weakening of the grain and phase boundaries. It appears that two processes take place under the effect of irradiation: a strengthening associated with the formation of defects and blocking of dislocations, and a softening caused by changes in the grain and phase boundaries. Prolonged radiation with numerous impacts of fast neutrons increases the number of lattice distortions and, as a result, strengthens the metal. With short exposures, only a few lattice defects are formed and, as a result, the softening process prevails. Orig. art. has: 4 figures. [ND]

TITLE: Softening of cast iron on irradiation with neutrons (Presented for discussion)

SOURCE: Liteynoye proizvodstvo, no. 6, 1966, 32

TOPIC TAGS: metal softening, neutron, radiation, cast iron, wear resistance, water moderated reactor

ABSTRACT: Normally, the neutron irradiation of metals increases their strength and reduces their plasticity. However, the irradiation of certain alloys with relatively small neutron doses in a conventional nuclear reactor without special cooling and in the presence of gamma radiation may lead to some softening of these alloys. This has been observed for not only alloys in work-hardened or annealed state but also for annealed malleable cast iron. Thus, the authors exposed groups of specimens of malleable cast iron, annealed for 34 hr at 970°C, to integral fluxes of  $10^{16}$ ,  $10^{17}$ ,  $10^{18}$ ,  $10^{19}$ , and  $10^{20}$  neutrons/cm<sup>2</sup> in a water-moderated reactor.

Card 1/3

UDC: 620.193.6:669.131.2

L 40796-66

ACC NR: AP6019714

-ted water-cooled reactor. Before and after the irradiation the specimens were tested for linear wear  $W$ , friction coefficient  $\mu$  and temperature  $t$  of the lubricant emerging from the friction zone, Vickers hardness, and microhardness. The wear tests showed that  $W$ ,  $\mu$  and  $t$  are hardly affected by irradiation. (It is noteworthy, however, that  $W$  increases markedly in the presence of  $10^{18}$  neutrons/cm $^3$ , although it eventually again returns to normal.) Hardness, as a yardstick of plastic deformation, is a characteristic of the wear resistance of materials. The pattern of variation in the hardness of the irradiated malleable and high-strength cast irons resembles the pattern of variation in their wear resistance. Thus (Fig. 1) hardness decreases following

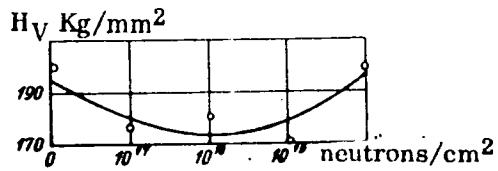

Fig. 1.

the irradiation of malleable cast iron with insignificant neutron fluxes ( $10^{17}$  -  $10^{18}$  neutrons/ $\text{cm}^2$ )

Card

2/3

L 40-96-66

ACC NR: AP6019714

but increases again as the neutron dose is increased. A similar pattern of variation in micro-hardness is observed. Evidently this is associated with the softening of the pearlitic component, since the hardness of the ferritic component increases monotonically with irradiation. It appears that the softening of annealed cast iron and various steels in the presence of low neutron doses is attributable to defects caused in the crystal lattice of the material by the neutron. As regards cast iron, a definite role is played by the cementite and ferrite grain boundaries, which apparently get weakened by the defects introduced by neutron irradiation, when these defects migrate toward grain boundaries. Thus, irradiation is accompanied by two simultaneous processes: softening of the material due to the weakening of grain boundaries and hardening of the crystal lattice in proportion to the number of the bombarding fast neutrons. As irradiation time increases, the hardening process begins to predominate. Orig. art. has: 3 figures.

TITLE: Hysteresis of antifriction properties of materials under conditions of boundary friction in heating and cooling

SOURCE: AN UkrRSR. Dopovidi, no. 8, 1966, 1015-1017

TOPIC TAGS: hysteresis, antifriction property, boundary friction

ABSTRACT: The author shows that external heating followed by subsequent cooling produces hysteresis in the antifriction properties of materials in friction. This is explained by the fact that for a period of time the contacting surfaces retain the physicomechanical properties which are true for higher temperatures. This is due to phase transformations in the structure of the metal at the surface of contact. The article was presented by Academician I. M. Fedorchenko of the AN UkrRSR.

Warsaw-Krakow, Przegląd Lekarski, Vol 19, Ser II, No 4, 63, pp 222-224.

Abstract: [Authors' Russian summary] In the course of investigating experimentally the reaction of bone tissue to various viruses, the authors found that both the S<sub>47</sub> strain and the equine encephalitis virus of the American West are pathogenic to white mice on intramedullary inoculation, and S<sub>47</sub> retained in the bone tissue even 10 days after inoculation in lethal quantities, even though encephalitis has already set in. Six Polish and one English references.

Warsaw-Krakow, Przeglad Lekarski, Vol 19, Ser II, No 5, 22 May 63, pp 249-254

**Abstract:** [Authors' English summary modified] Inoculation of K<sub>24</sub> strain of tick-borne encephalitis virus into the bone marrow of white mice produced pathogenic changes in the bone, with hemorrhagic effusion, necrosis of the bony tissue, and regeneration by chondromatous metaplasia. Medullary hyperplasia is characteristic. Radiological changes appear on one side nine days after inoculation and spread to the other side. Two each Polish and English references.
